RESEARCH INTEREST

I am enthusiastic about nearly all aspects of astrophysics and cosmology. Some of them are listed below.

- Probing outskirts of galaxies, intracluster lights and ultra-diffuse galaxies using deep sky surveys
- Quenching process of disk galaxies
- Cosmology, large-scale structure, weak lensing
- Application of statistical methods and machine learning in astrophysics

RESEARCH EXPERIENCE

Reaching for the Edge: Probing the Outskirts of Massive Galaxies with HSC, DECaLS, SDSS and Dragonfly
Advisor: [Alexie Leauthaud](#), [Song Huang](#) Sept, 2018 - Now

Probing the outskirts of massive galaxies can reveal the relation between galaxy itself and its dark matter halo. To push the detection limit of galaxy outskirt forward, we are using Hyper Suprime-Cam Subaru Strategic Survey (HSC-SSP) images and already get down to 29 mag/arcsec² and ~ 150 kpc. Furthermore, we compare HSC with Dark Energy Camera Legacy Survey (DECaLS) and Dragonfly Telephoto Array, try to find the difference between surveys as a correction. This work may help correct the previous galaxy mass measurements, and examine the existed relations on galaxy-halo connection.

SDSS IV MaNGA: Inside-out quenching galaxies with H α ring-like structures

Advisor: [Yingjie Peng](#) July, 2017 - Now

We investigated galaxies with H α emission ring-like structures in Mapping Nearby Galaxies at APO (MaNGA) survey, with stellar mass in the range $9 < \log(M/M_{\odot}) < 12$. These galaxies are almost located in the green valley on SFR-stellar mass plane. The radius of H α rings are measured and good linear relations between bar length and H α ring radius are found. We reveal that the appearance of H α star-forming ring-like structure has a strong correlation with bar-induced activities. The majority of our H α

ring galaxy sample are galaxies which are classified as LINER with $EW(H\alpha) < 3\text{\AA}$. Low luminosity AGN possibly plays a role in inside-out quenching accompanying with $H\alpha$ ring-like structure.

Multi-resolution filtering: an empirical method for isolating faint, extended emission in Dragonfly data and other low resolution images

Advisor: [Pieter van Dokkum](#)

June, 2019 - Sept, 2019

We developed an empirical, self-contained method to isolate and study faint, large-scale emission in imaging data of low spatial resolution. Multi-resolution filtering (MRF) uses independent data of superior spatial resolution to create a model for all compact and high surface brightness objects in the field. The resulting image only contains emission fainter than a pre-defined surface brightness limit. The method is implemented in [mrf](#), an open-source MIT licensed Python package
